Python is a versatile programming language whose usage has been increasing over the years. Although it is considered rather simple, learning it for someone who has never studied programming can be complex.

The Snake Project website aims to offer users a computer challenge where they can code a very simple bot in Python and have it compete against other players' bots in 1v1 matches.

The project is heavily inspired by the Codingame website, particularly the Tron Battle puzzle.

The application should allow users to code, test, implement, and evaluate the performance of several bots entirely coded in Python and using Python's standard library.

In case of syntax errors, users should be able to see the error and the line where it occurs. In case of a crash, the user should be able to view the logs as if they were coding the bot on their own machine.

Bots receive information about the current game through standard input. They make decisions (the direction in which they move) through standard output. They can also send messages through standard error output.

Users can create bots, publish or unpublish them, edit them, delete them, and view their matches. Matches take place on a grid of twenty (20) lines and thirty (30) columns. The user can navigate to a certain part of the match to analyze the behavior of their bot or that of the opponent.

However, a user cannot view the source code of opposing bots. But they can view their standard output.

The site also has a forum where users can read and communicate with each other via topics.

A user can also modify their account information: change their login ID, password, or add two-factor authentication.

A user can also delete their account if they wish. This deletion also removes all of their bots.

The website is built using the Django framework.
